

20.109 Spring 2016 Module 2 – Lecture 4

System Engineering (March 29th 2016)

Noreen Lyell
Leslie McLain
Maxine Jonas
Jing Zhang(TA)

Leona Samson (Lectures)

Zachary Nagel (help with development) Alex Chaim

Key Experimental Methods for Module 2

- Mammalian tissue cell culture
- Monitoring protein level by Western blot
- **Generating plasmids with DNA damage**
- Transfecting plasmids into mammalian cells
- **Using fluorescent proteins as reporters of biological processes**
- Flow cytometry to measure DNA repair
- Statistical analysis of biological data

The diversity of fluorescent proteins and genetic mutations is illustrated by this San Diego beach scene drawn with living bacteria expressing 8 different colors of fluorescent proteins.

Basis for the fluorescent reporter assay:

Following digest, the substrate contains a DSB in the 5' UTR that prevents fluorescent reporter expression

NHEJ HCR in WT and NHEJ defective cells at 18 hours post-transfection:

What experimental question will you ask in Module 2?

How efficiently does DNA repair by the Non Homologous End Joining (NHEJ) pathway act on DNA damage with different topologies?

This raises the following questions

- How does DNA get damaged?
- What is DNA repair?
- Why does DNA repair exist?
- **Why do we care about how efficient DNA repair is?**
- How does one actually measure DNA repair efficiency?

How does the cell decide which pathway to use?

Cancers arise from the accumulation of heritable changes in gene function

Multiple Mutations

More and more Mutations

The Genetic Basis of Cancer and Theodor Boveri 1862 - 1915

The Boveri.

- Established that chromosomes carry the hereditary information by showing that aberrant segregation of chromosomes leads to certain phenotypes in sea urchin eggs.
- Suggested that aberrant segregation of human chromosomes could be responsible for a normal cell becoming a tumor cell
- Suggested that some chromosomes promoted cell growth and others inhibit cell growth

Marcella O'Grady Boveri (1865-1950) also contributed

- Suggested that some chromosomes promoted cell growth and others inhibit cell growth

Marcella O'Grady Boveri (1865-1950) also contributed

Alterations (mutations) in different kinds of Genes cause Cancer

Oncogenes

genes that ordinarily promote cell proliferation but when mutated or overexpressed promote uncontrolled growth

Tumor suppressor genes

genes that ordinarily prevent inappropriate proliferation but when mutated allow uncontrolled growth

Mutator genes

genes that ordinarily prevent mutations; alterations in these genes allow increased mutation rates

Lack of DNA repair accelerates the onset of cancer

Mechanisms of Chromosome Translocation

Nature Reviews Cancer **13**, 443–454 (2013)

a | Balanced reciprocal translocations from the fusion of two double-strand breaks that arise in the same cell; ligation of the free DNA ends is mediated by the **non-homologous end-joining pathway**. Red and blue strands represent different chromosomes.

b | Telomere uncapping or attrition generates a DNA double-strand break response, which potentially leads to the fusion of telomeres, generating end-to-end fusions. During anaphase, dicentric fusion chromosomes are pulled apart, leading to the formation of translocations and double-strand breaks. Broken chromosomes act as substrates for additional rounds of fusion and breakage, generating increasingly complex translocations.
