

Lecture 3

The MAX transcription factor (and why we want chemical probes)

February 22, 2024

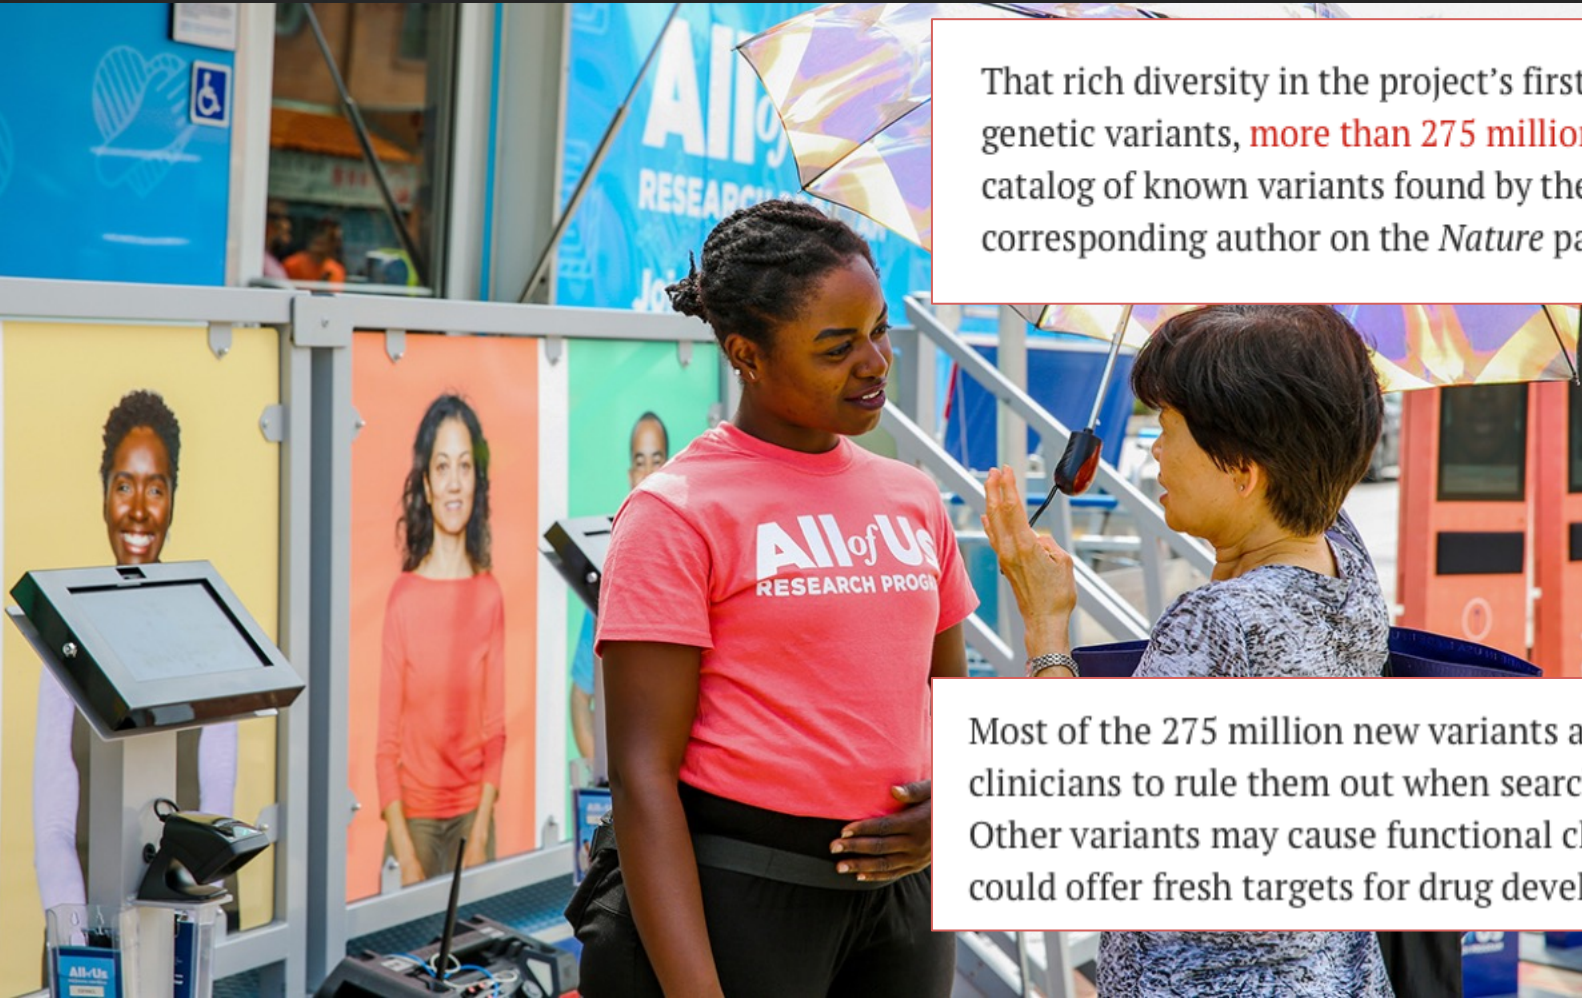

Quarter-million genomes analyzed in NIH project could be 'hugely important' for identifying disease risks

All of Us finds many millions of new DNA variants as it moves toward 1 million participants from diverse backgrounds

Science

19 FEB 2024 • 11:00 AM ET • BY JOCELYN KAISER

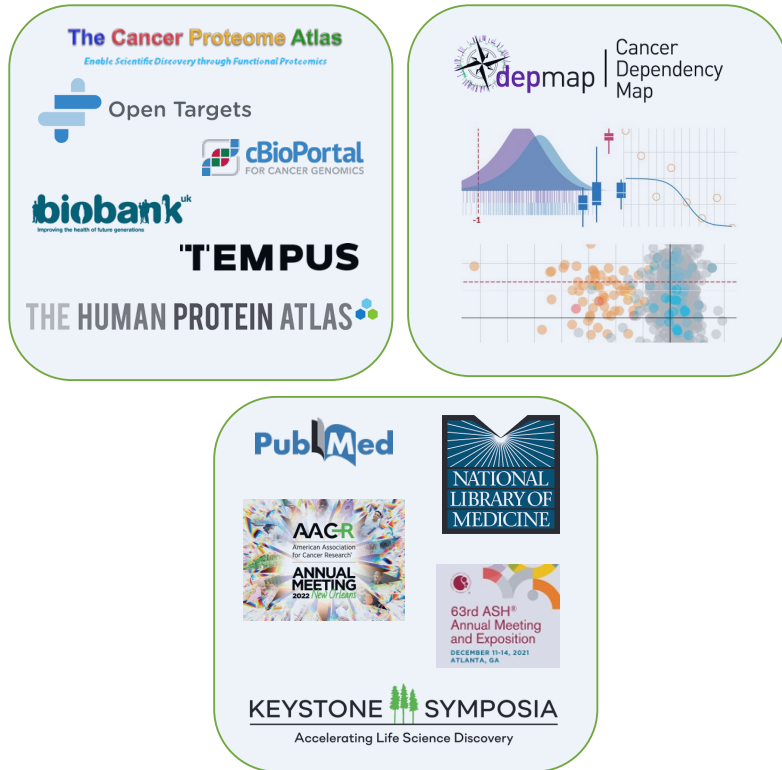

A photograph showing two women at a research booth. The woman on the left is wearing a bright pink t-shirt with the 'All of Us' logo and is looking towards the woman on the right. The woman on the right is wearing a patterned top and is gesturing with her hand while speaking. In the background, there are colorful posters and a sign that says 'All of Us RESEARCH PROGRAM'.

That rich diversity in the project's first 245,388 whole genomes revealed more than 1 billion genetic variants, **more than 275 million of which were novel**. This expands by roughly 30% the catalog of known variants found by the UK Biobank and other whole genome databases, says Bick, corresponding author on the *Nature* paper.

Most of the 275 million new variants are rare, and many could prove harmless, which would allow clinicians to rule them out when searching for the gene behind a child's disease, for instance. Other variants may cause functional changes in a gene's protein that in turn trigger disease and could offer fresh targets for drug development.

From Lecture 1 (again): Therapeutically-driven probe discovery

assess tractability of emerging target candidates

cell lines and patient samples
reveal list of disease genes

test impact of disease
genes in a physiologic settings

chemical probe

discover molecules that reverse
impact of disease genes

The Cancer Dependency Map

interrogation of viability effects in cancer cell lines to map genetic dependencies

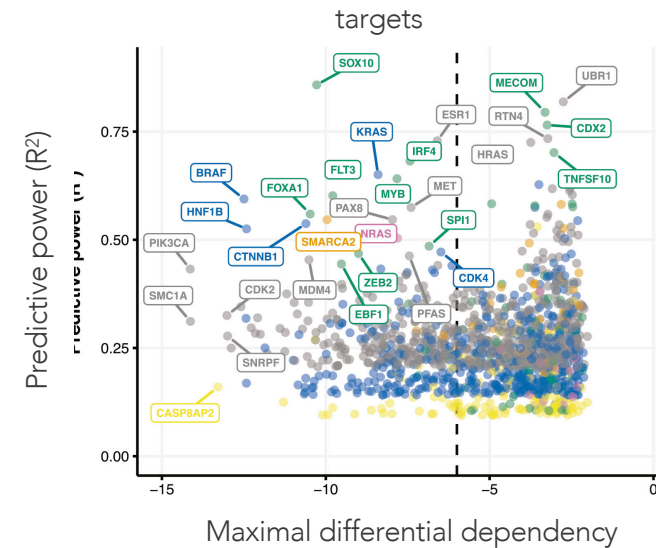

patient models (cell lines/organoids)
representing many tumors

molecular and
genetic information

genetic dependencies and
drug sensitivities

Discovery of potential **TARGETS** for therapeutic discovery

Discovery of **PREDICTORS** of patient response

Pre-publication **DATA RELEASES** to enable the scientific community at depmap.org

As of 4/21/22:

>2,000 cancer models

3913 genetic dependency screens

33 drug panels in sensitivity screens

Dependent Cell Lines

CRISPR: 42/558 **STRONGLY SELECTIVE**
 RNAi: 11/711 **STRONGLY SELECTIVE**

Dependency Score: Outcome from DEMETER2 or CERES. A lower score means that a gene is more likely to be dependent in a given cell line. A score of 0 is equivalent to a gene that is not essential whereas a score of -1 corresponds to the median of all common essential genes.

Strongly Selective: A gene whose dependency is at least 100 times more likely to have been sampled from a skewed distribution than a normal distribution (i.e. skewed-LRT value > 100).

Stabilization of the Max Homodimer with a Small Molecule Attenuates Myc-Driven Transcription

Graphical Abstract

koehler@mit.edu

In Brief

Myc/Max-mediated transcription is deregulated in most of human cancers. Struntz et al. discovered a small molecule that stabilizes the Max homodimer and attenuates Myc-driven transcription with efficacy in cellular and murine cancer models. This discovery reinforces an alternative Myc-targeting strategy and could inform development of compounds to treat Myc-dependent cancers.

Highlights

- KI-MS2-008 is a Max-binding small molecule that attenuates Myc-driven transcription
- The compound stabilizes the Max homodimer
- Effects on DNA occupancy and the transcriptome resemble loss of Myc
- Treatment with KI-MS2-008 exhibits efficacy in cellular and murine cancer models
